why is offline zone enumeration possible with **NSEC3**?

Because resolvers can compute hashes offline.

Step 1: Collect

a1bb5.com

dde45.com

23ced.com

A) Make dictionary

B) Hash each name

$H(a.com) = a1bb5$

$H(b.com) = 33333$

....

$H(z.com) = dde45$

NSEC5 replaces the hash **H** with a **Verifiable Random Function (VRF)** that resolvers cannot compute offline.

- * **NSEC5-RSA:** π is a deterministic RSA signature
- * **NSEC5-ECC:** new construction based on elliptic curves
 - π is implicit in [Goh-Jareki'02][FranklinZhang'13]
 - We prove it's a VRF.
 - For 256-bit elliptic curves, π gives 641-bit outputs.

recursive resolver

Two versions of NSEC5:

1. NSEC5-RSA from **[NDSS'15]**
 - The VRF proof is a deterministic RSA signature (2048 bits)
2. New NSEC5-ECC:
 - For 256-bit elliptic curves, the VRF proof is 641 bits.

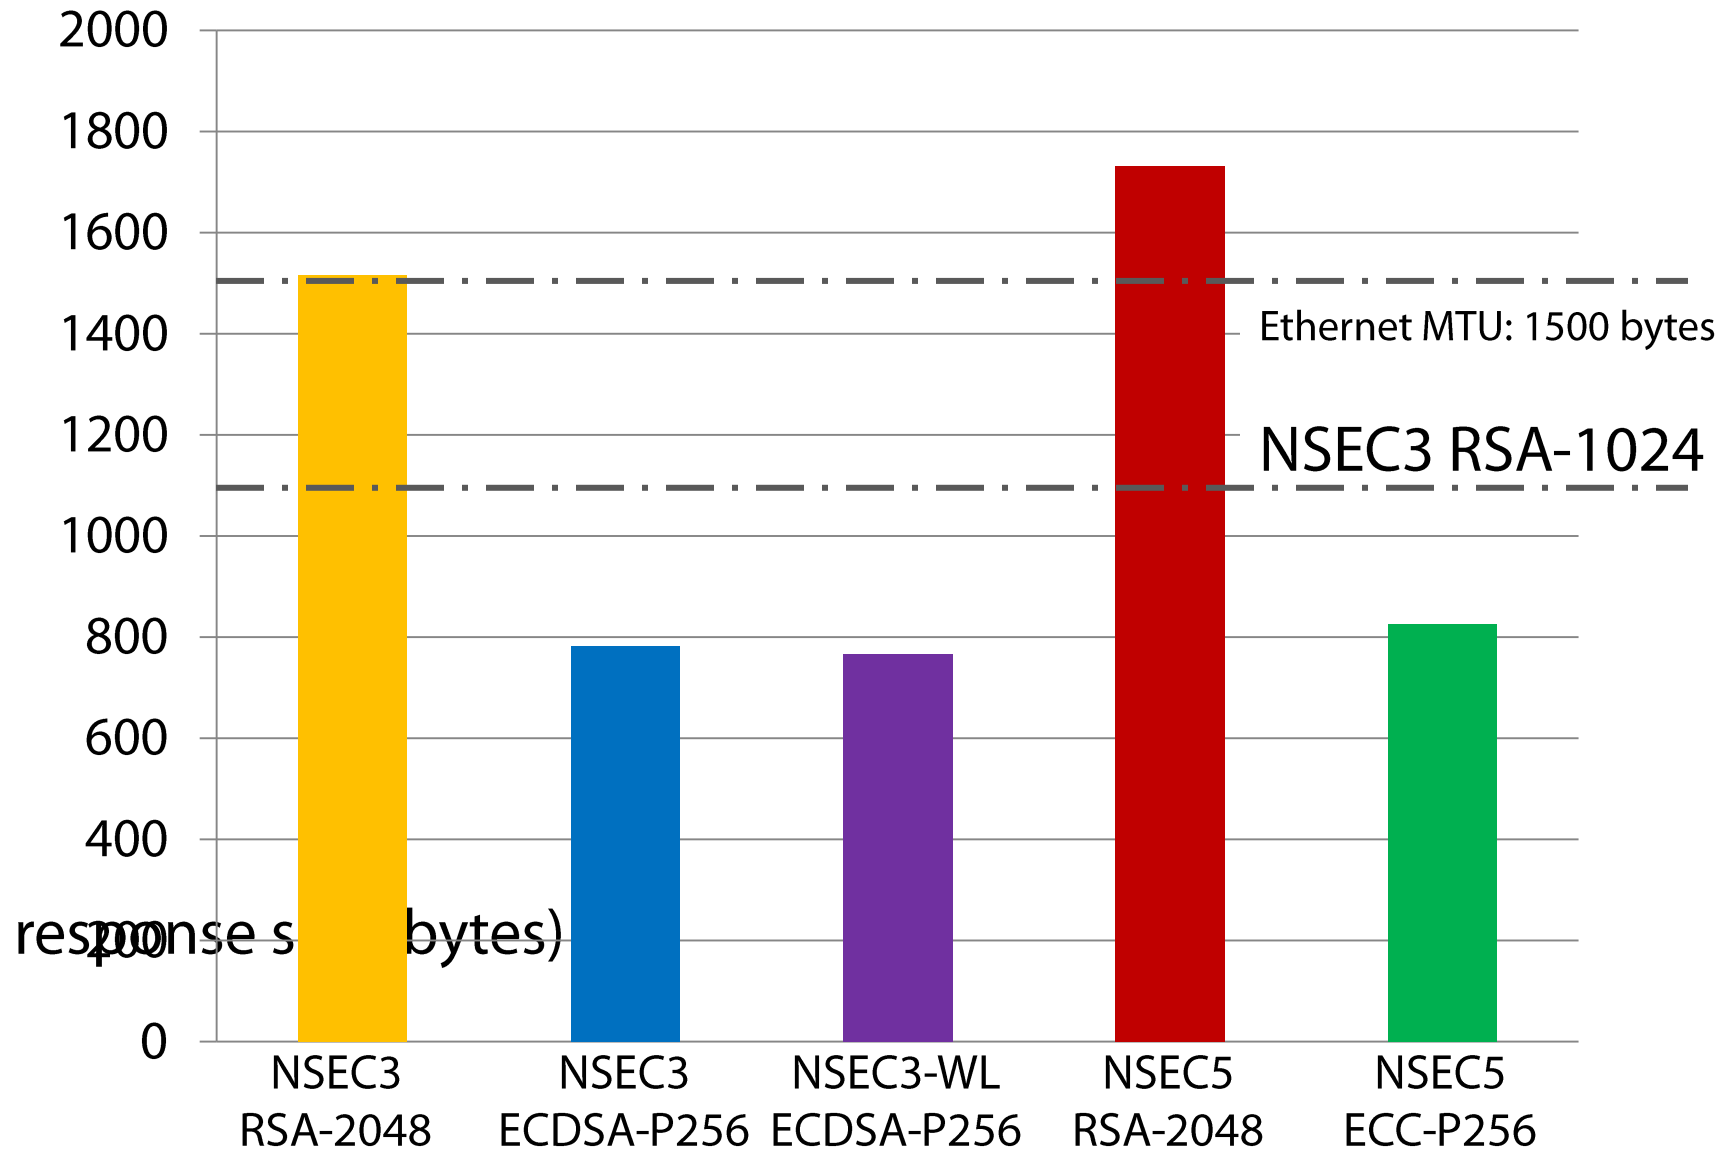

We use unstandardized optimizations developed for NSEC3

1. The wildcard bit **[GiebenMekking'12]**
2. Precomputed closest encloser proofs

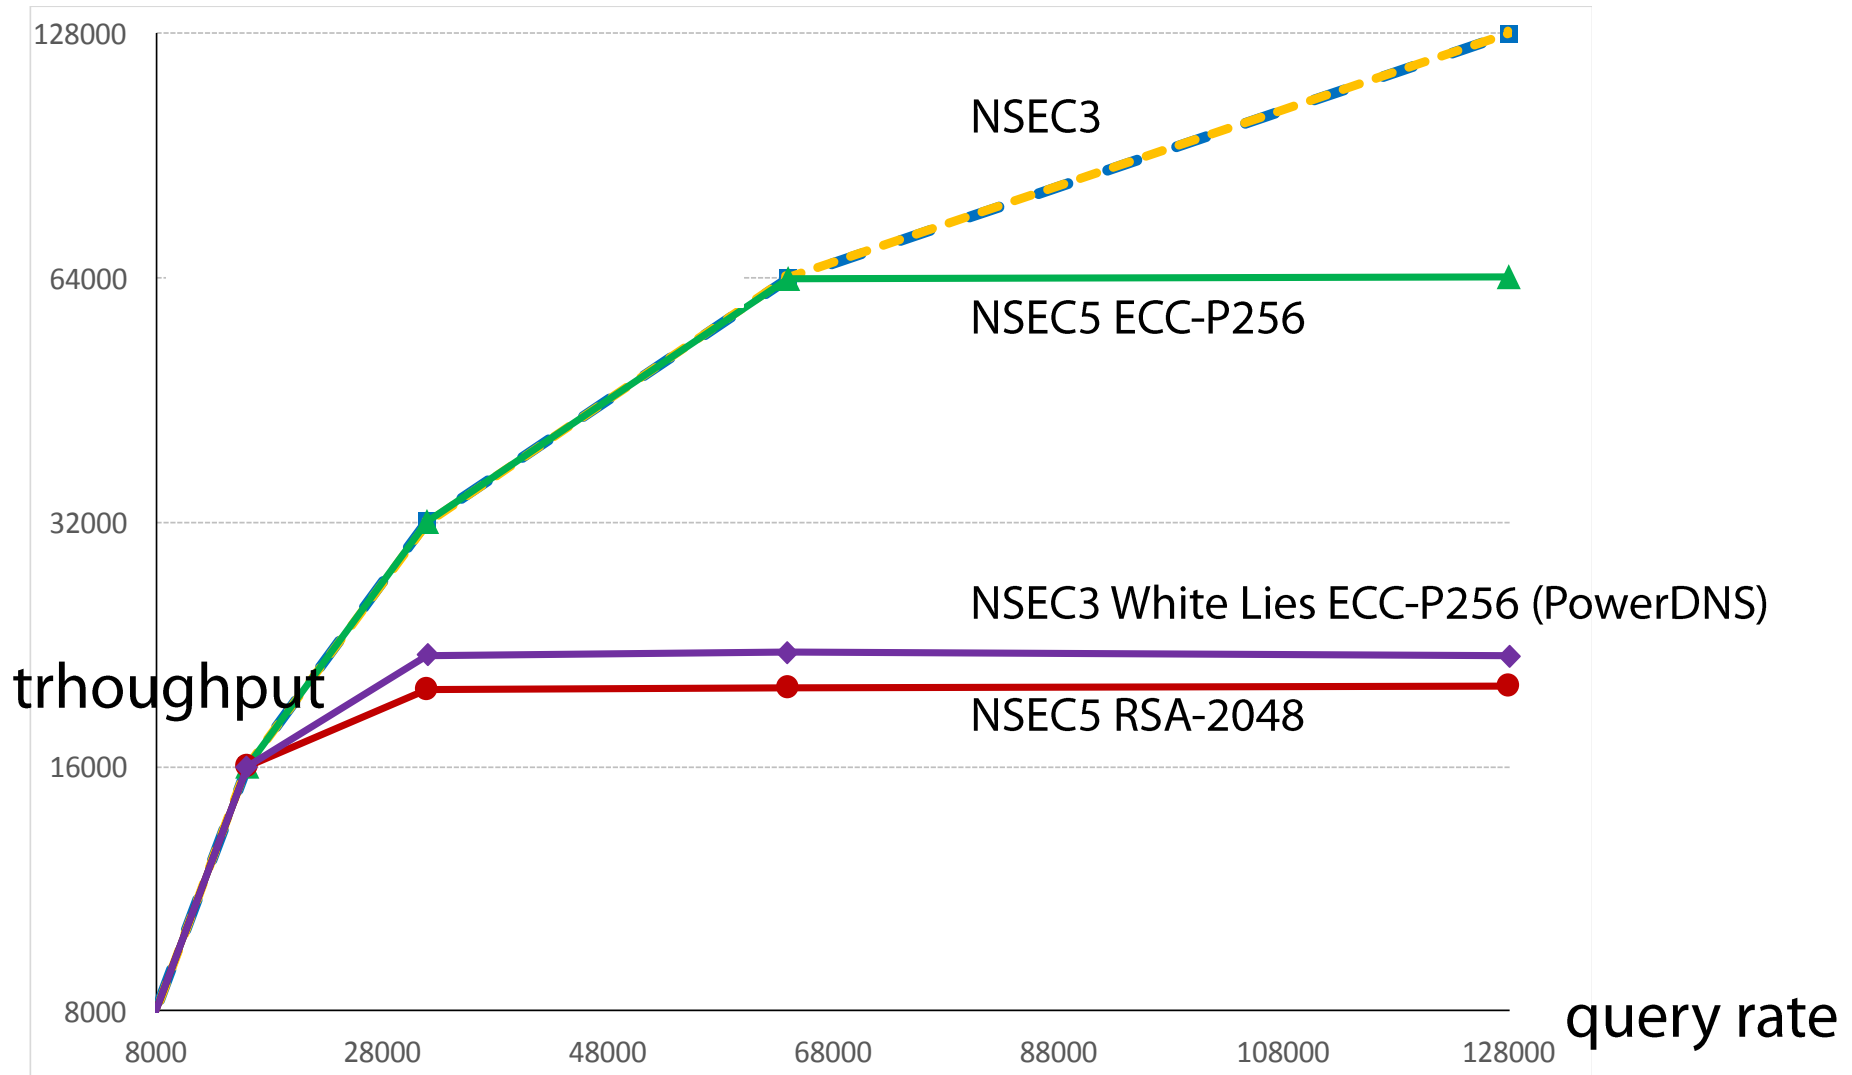

9K Lines of Code, no new libraries (openSSL) or system optimizations

Hearing about NSEC5

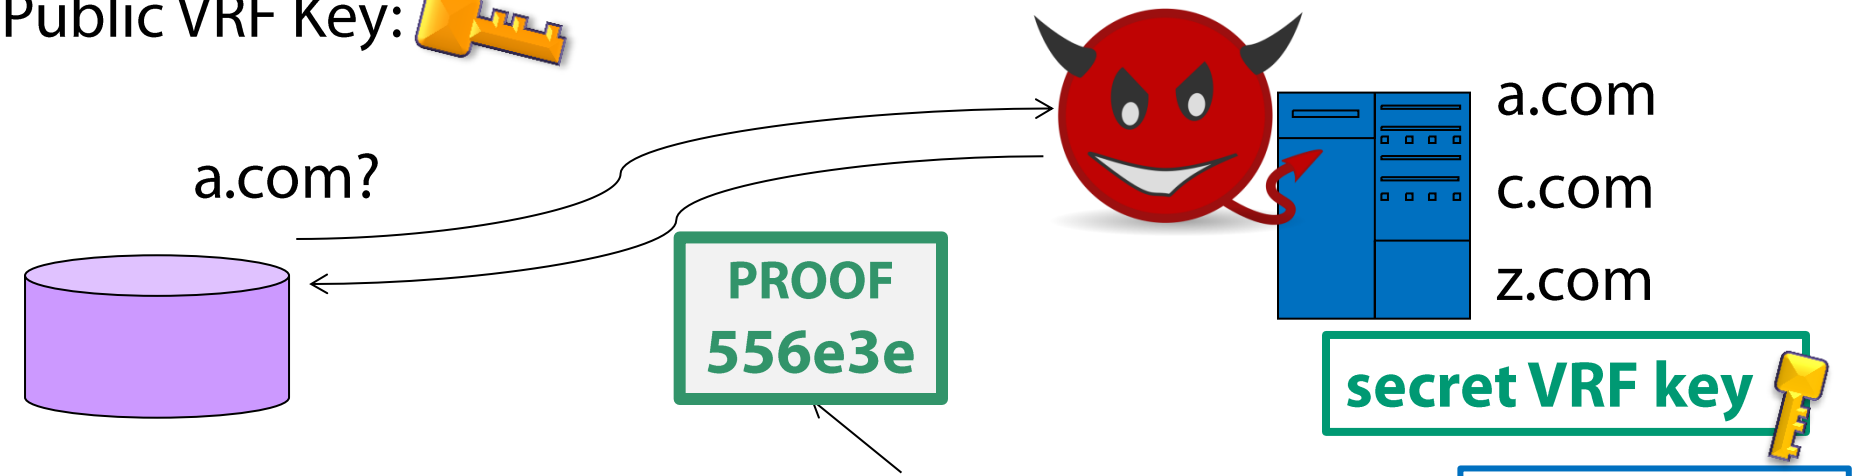

When I finally grasp NSEC5

why NSEC5 has integrity even if secret VRF key is lost

Public Zone Signing Key (ZSK): 

Public VRF Key: 

The proof is unique given the public VRF key. It must be correct b/c resolvers validate it!

! Don't know secret ZSK,
• so can't forge NSEC5s

! There is no covering
• NSEC5 to replay, since
 $H(556e3e)=9ae3e$

Public parameters. Let q be a prime number, Z_q be the integers modulo q , $Z_q^* = Z_q - \{0\}$, and let G a cyclic group of prime order q with generator g . We assume that q, g and G are public parameters of our scheme. Let H_1 be a hash function (modeled as a random oracle) mapping arbitrary-length bitstrings onto the cyclic group G . (See Appendix A for a suggested instantiation of H_1 .) Let H_3 be a hash function (modeled as a random oracle) mapping arbitrary-length bitstrings to fixed-length bitstrings. We can use any secure cryptographic function for H_3 ; in fact, we need only the first ℓ bits of its output for ℓ -bit security. Let H_2 be a function that takes the bit representation of an element of G and truncates it to the appropriate length; we need a 256 bit output for 128-bit security.

Keys. The secret VRF key $x \in Z_q$ is chosen uniformly at random. The public VRF key is g^x .

Hashing. Given the secret VRF key x and input α , compute the proof π as:

1. Obtain the group element $h = H_1(\alpha)$ and raise it to the power of the secret key to get $\gamma = h^x$.
2. Choose a nonce $k \in Z_q$.
3. Compute $c = H_3(g, h, g^x, h^x, g^k, h^k)$.
4. Let $s = k - cx \bmod q$.

The proof π is the group element γ and the two exponent values c, s . (Note that c may be shorter than a full-length exponent, because its length is determined by the choice of H_3). The VRF output $\beta = F_{SK}(\alpha)$ is computed by truncating γ with H_2 . Thus

$$\pi = (\gamma, c, s) \quad \beta = H_2(\gamma)$$

Notice that anyone can compute β given π .

Verifying. Given public key g^x , verify that proof π corresponds to the input α and output β as follows:

1. Given public key g^x , and exponent values c and s from the proof π , compute $u = (g^x)^c \cdot g^s$.
Note that if everything is correct then $u = g^k$.
2. Given input α , hash it to obtain $h = H_1(\alpha)$. Make sure that $\gamma \in G$. Use h and the values (γ, c, s) from the proof to compute $v = (\gamma)^c \cdot h^s$. Note that if everything is correct then $v = h^k$.
3. Check that hashing all these values together gives us c from the proof. That is, given the values u and v that we just computed, the group element γ from the proof, the input α , the public key g^x and the public generator g , check that:

$$c = H_3(g, H_1(\alpha), g^x, \gamma, u, v)$$

Finally, given γ from the proof π , check that $\beta = H_2(\gamma)$.

Figure 2: An EC-based VRF for NSEC5. We use a multiplicative group notation. This VRF adapts the Chaum-Pederson protocol [28] for proving that two cyclic group elements g^x and h^x have the same discrete logarithm x base g and h , respectively.
